GENDER SEGREGATION AND MALE DOMINANCE

What does the literature say?

- men exhibit stronger gender homophily, while women collaborate more evenly across genders (McNichols et al. 2020; Kwiek and Roszka 2021; Wang et al. 2023; L  ther and Freund 2024)
- this limits diversity and reinforces gender imbalances in academic networks further hindering women's career progression, visibility and access to resources (Uhly et al. 2017; Kwiek and Roszka 2021; Berggren et al. 2022)

WHO'S ON THE TEAM?

PUBMED AS A DATA SOURCE

- What is PubMed?**
- free, searchable database of biomedical and life sciences literature
 - >18 million authors of > 31 million articles from 1781 to 2021
 - analytical sample for this study: >400.000 authors and >1.1 million papers

TO THE FUTURE
This study provides indicative evidence that male researchers exhibit stronger gender homophily, frequently collaborating in all-male teams and forming distinct all-male clusters within the networks. But further research needs to consider gender diversity and measure homophily and inequality more directly.
